# KS Sputter bearings – O.E. quality for the aftermarket

As an approved series supplier of all renowned automotive and engine manufacturer KS in Germany produces Sputter bearings as original equipment (O.E.) and for the global aftermarket. The following table shows an extract of our comprehensive range of Sputter bearings.

### Development and introduction of Sputter bearings

Sputter bearings were first used in modern engine construction in 1989. The launch of newly developed and extremely efficient diesel engines with high torques which subjected engine bearings with increasing specific stresses meant that the limits of galvanic surface coating technology had been reached. For this reason, new bearing materials and coating methods were investigated and developed. An increased bearing stress capacity of up to 50% was achieved with bearings of identical dimensions and materials that were coated with the Sputter method. In addition, immensely improved wear resistance was accomplished solely by changing the coating processes.

#### The Sputter process

The special surface of the Sputter bearing is generated by means of the PVD or Physical Vapour Deposition method. This process is carried out in a high vacuum under clean-room conditions. In this process, atoms are ejected from a target (coating material) by accelerated argon gas ions which are then deposited on the running layer of the bearing shell. The highly stress-resistant sliding surface of the bearing is formed as a result of the extremely fine distribution of the coating material. The ultimate layer is only a few thousandth of millimetre thick. There is no galvanic procedure that can achieve such fine and consequently extremely resistant sliding layers. Sputtering a bearing shell

takes between 7 and 10 hours, depending on the layer thickness of the sliding surface. As a result of the complex and extremely long coating time as well as the labour-intensive pre-cleaning steps, the production of a sputtered bearing shell is far more expensive than the manufacture of conventional three-component bearing shells.

The right of changes and deviating pictures is reserved. For exact details about applications, please refer to our current catalogue / CD / OnlineShop.

# Bearing production and production capacities

KS Gleitlager GmbH have consistently expanded the production capacities for Sputter technology. Of the 110 million bearings manufactured annually in the KS bearings plant in Papenburg, more than ten million are Sputter bearings. These extremely stress-resistant bearings can withstand the extreme working pressures that are generated in modern diesel and petrol engines. As a result of the start-up of a planned third Sputter plant together with the new development of lead-free high-performance bearing materials, the KS brand is optimally prepared for oncoming market developments in the original equipment and aftermarket sector. Thanks to increased production capacities and higher output figures it has been possible to consistently reduce production costs in recent years.
